

ASSIGNMENT 7

Aim: Insert the keys into a hash table of length m using open addressing using double hashing with $h(k)=(1+k\text{mod}(m-1))$.

Objective: To study and learn the concepts of double hashing.

Theory:

Double hashing is a collision resolving technique in Open Addressed Hash tables. Double hashing uses the idea of applying a second hash function to key when a collision occurs.

Double hashing can be done using: $(\text{hash1}(\text{key}) + i * \text{hash2}(\text{key})) \% \text{TABLE_SIZE}$
Here $\text{hash1}()$ and $\text{hash2}()$ are hash functions and TABLE_SIZE is size of hash table.
(We repeat by increasing i when collision occurs)

First hash function is typically $\text{hash1}(\text{key}) = \text{key} \% \text{TABLE_SIZE}$

A popular second hash function is:

$\text{hash2}(\text{key}) = \text{PRIME} - (\text{key} \% \text{PRIME})$ where PRIME is a prime smaller than the TABLE_SIZE .

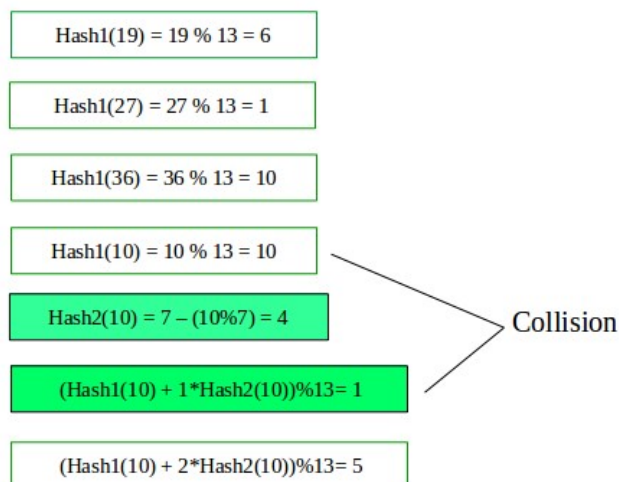

A good second Hash function is:

- It must never evaluate to zero
- Must make sure that all cells can be probed

Algorithm:

Lets say, **Hash1 (key) = key % 13**

Hash2 (key) = 7 – (key % 7)

Program:

```
#include<iostream>

#include<string>

using namespace std;

class Hash

{

int k;

int ht[10];

public:

Hash()

{

for(int i=0; i<10;i++)

{

ht[i]= -1;

}

}

void insert()

{

int k;

cout<<"Enter Key ";

cin>>k;

int pos1, pos2, pos;

pos1 = (k) % 10;

if (ht[pos1] ==-1)

{

ht[pos1] = k;
```

```
}  
  
else  
  
{  
  
pos2=(7 - (k % 7));  
  
int i = 1;  
  
    while (1)  
  
    {  
  
        int pos = (pos1 + i * pos2) % 10;  
  
        if (ht[pos] == -1)  
  
        {  
  
            ht[pos] = k;  
  
            break;  
  
        }  
  
        i++;  
  
    }  
  
}  
  
}  
  
void display()  
  
{  
  
for(int i=0; i<10; i++)  
  
{  
  
cout<<i << "\t" << ht[i] <<endl;  
  
}  
  
}  
  
};
```

```
int main()
{
    Hash h;
    int ch;
    char choice;
    do
    {
        cout << "1. Insert key " << endl;
        cout << "2. Display table " << endl;
        cout << "Enter your choice " << endl;
        cin >> ch ;
        switch ( ch )
        {
            case 1:
                h.insert();
                break;
            case 2 :
                h.display();
                break;
            default :
                cout << "\tINVALID CHOICE " << endl;
        }
        cout << "\tDo you wish to continue (y/n) " << endl;
        cin >> choice ;
    } while ( choice == 'y');
}
```

Output:

```
"C:\Users\n\Desktop\sem2\sd\Assignment 7\assignment 7.exe"
1. Insert key
2. Display table
Enter your choice
1
Enter Key 34
Do you wish to continue (y/n)
y
1. Insert key
2. Display table
Enter your choice
1
Enter Key 67
Do you wish to continue (y/n)
y
1. Insert key
2. Display table
Enter your choice
14
INVALID CHOICE
Do you wish to continue (y/n)
y
1. Insert key
2. Display table
Enter your choice
1
Enter Key 4
Do you wish to continue (y/n)
y
1. Insert key
2. Display table
Enter your choice
2
0      4
1      -1
2      -1
3      -1
4      34
5      -1
6      -1
7      67
8      -1
9      -1
Do you wish to continue (y/n)
```

Conclusion:

We successfully implemented open addressing using double hashing.

It is a better collision resolution technique compared to single hashing, since it has less number of collisions.
